1 Introduction

Autonomous driving is an emerging technology that enables the reduction of traffic accidents and allows for those who are unable to drive for various medical conditions to regain their independence, by performing intelligent perception and planning based on multimodal sensors such as LIDARs, cameras, IMUs and GPS. It is critical for an autonomous vehicle to perform precise, robust localization for decision making as it is a sub-system that cannot fail during online autonomous operation. There have been a large amount of research efforts focused on multi-sensor fusion for localization [1], which has reached a certain level of maturity, yielding a bounded problem given the well structured environment a vehicle operates in. In particular, graph-based optimization has recently prevailed for robot mapping and localization [2]. Due to the different sampling rates of the heterogeneous sensors, measurements arrive at different times. Accurate alignment of such out-of-sequence (i.e., asynchronous) measurements before optimally fusing them through graph optimization, while essential, has not been sufficiently investigated in the literature. It should be noted that the asynchronous measurement alignment under consideration is different from the time synchronization (or temporal sensor calibration) [3]; that is, even if sensors are well synchronized, their observations still arrive asynchronously.

Factor graph-based formulation [4] is desirable due to its ability to allow for the delayed incorporation of asynchronous measurements. Indelman et al. [5] address the problem of the inclusion of asynchronous measurements by taking advantage of IMU preintegrated terms. This allows them to incorporate any set of asynchronous sensors whose rates are longer than that of the IMU. Sünderhauf et al. [6] looked to address the incorporation of measurements with unknown time delays. Using high frequency odometry measurements, they create a state for each incoming odometry measurement so that delayed factors can be directly connected to its closest state. While both of these can be used to address arbitrary amounts of delay between sensors, they add a large amount of additional factors and edges to the graph. In contrast, the proposed approach incorporates measurements of different frequencies without significant increase of the overall graph complexity. It should be noted that while this does reduce the computational cost of optimization, reductions in graph size are always welcomed as a robot’s physical memory becomes less of an issue.

From the theoretical perspective, as the main contribution of this paper, we accurately align both asynchronous unary and binary graph factors based on our analytically derived linear 3D pose interpolation. This interpolation allows for the direct addition of asynchronous measurements into the graph, without the need for extra nodes to be added or for the naive ignoring of the measurement delay. Patron-Perez et al. [7] first proposed a spline-based trajectory method that allows for the fusion of delayed measurements with the consequence of an increase of overall system complexity and deviation from a pure pose graph. Outside of graph-based optimization, interpolation has been used to correct time offsets of continuous measurements such as LIDAR point clouds and rolling shutter cameras [8, 9]. In particular, Guo et al. [9] introduced the idea of linear interpolation between past camera poses, which allow for the use of extracted features from rolling shutter cameras. Ceriani et al. [8] used a linear interpolation between two poses in $SE(3)$ to unwarp LIDAR point measurements. In this work, however, we focus on analytically deriving such $SE(3)$ interpolation and applying it inside of a graph-based optimization framework to allow for the efficient alignment of asynchronous measurements.

From the system perspective, we design and implement a modular framework for fusing a variety of sensors, where we separate the sensor fusion and pose estimation to allow for any sensor to be incorporated. This system design permits the easy incorporation of additional sensors, while also allowing for active sensor pose estimation modules to be changed without affecting the multi-sensor fusion. This is achieved by fusing emitted 3D pose estimates from sensor odometry (ego-motion)
modules. The proposed sensor framework can then leverage these 3D poses, emitted in their own local frame of reference, in the global estimation of the robot’s pose.

2 Key Related Works

2.1 Async Measurements in Batch Optimization

- Indelman et al. avoid the asynchronous measurement problem by inserting a new state into the graph and connecting it using IMU preintegration. Link
- Ranganathan et al. introduced a Dynamic Bayes Net for fixed-lag smoothing for processing out of sequence measurements with square-root smoothing. Link
- Sünderhauf et al. look at differences between ignoring the time delay, performing a maximum likelihood selection, and explicit delay estimation for handling the incoming measurement of unknown delay. They show that if these measurements are to be included directly into the graph, explicit delay estimation is most optimal. Link

2.2 Measurement Interpolation

- Patron-Perez et al. proposed a spline-based trajectory method that allows for the fusion of delayed measurements with the consequence of an increase of overall system complexity and deviation from a pure pose graph. Link
- Guo et al. introduce the idea of interpolation between past camera poses, allowing the use of rolling shutter measurements. Link
- Ceriani et al. use a linear interpolation between two SE3 poses to unwarp lidar point measurements. \( \Gamma_{12t} = \Gamma_1 \cdot \text{Expv} \left( t_s \cdot \text{Logv} \left( \Gamma_1^{-1} \Gamma_2 \right) \right) \). Link

3 Graph-based Estimation

\[
\hat{x} = \text{arg min}_x \sum_i ||r_i (x)||^2 P_i \tag{1}
\]

Figure 1: Example of a factor graph that our system created. States that will be estimated are denoted in circles and measurements are denoted in squares. Note that we differentiate interpolated factors with dashed outlines.

As the vehicle moves through the environment, a set of measurements, \( z \), is collected from its sensors, such as LIDAR scans, images, GPS, etc. These measurements relate to the underlying state to be estimated, \( x \). This process can be represented by a graph, where nodes correspond to parameters to be estimated (i.e., historical vehicle poses). Incoming measurements are represented as edges connecting their involved nodes (see Figure 1). Under the assumption of independent Gaussian noise corruption of our measurements, we formulate the Maximum Likelihood Estimation (MLE) problem as the following nonlinear least-squares problem [10]:

\[
\hat{x} = \text{arg min}_x \sum_i ||r_i (x)||^2 P_i \tag{1}
\]
where \( r_i \) is the zero-mean residual associated with measurement \( i \), \( P_i \) is the measurement covariance, and \( \|v\|^2_P = v^T P^{-1} v \) is the energy norm. This problem can be solved iteratively by linearizing about the current estimate, \( \hat{x}^- \), and defining a new optimization problem in terms of the error state, \( \Delta x \):

\[
\Delta x^- = \arg \min_{\Delta x} \sum_i \| r_i (\hat{x}^-) + H_i \Delta x \|^2_{P_i} \tag{2}
\]

where \( H_i = \frac{\partial r_i (\hat{x}^- \oplus \Delta x)}{\partial \Delta x} \) is the Jacobian of \( i \)-th residual with respect to the error state. We define the generalized update operation, \( \oplus \), which maps a change in the error state to one in the full state. Given the error state \( \{ \hat{\theta}_i, \hat{\phi}_i \} \), this update operation can be written as \( \{ \text{Expv} (-i \hat{\theta}) R, G \hat{p}_i + G \hat{\phi}_i \} \) (note that notation and identities can be found in Appendix A). After solving the linearized system, the current state estimate is updated as \( \hat{x}^+ = \hat{x}^- \oplus \Delta x^- \).

In this work, we parameterize the pose of each time step as \( \{ iG R, iG p \} \), which describes the rotation from the global frame \( \{ G \} \) to the local frame \( \{ i \} \) and the position of the frame \( \{ i \} \) seen from the global frame \( \{ G \} \) of reference. This linearization process is then repeated until convergence.

While there are openly available solvers [11, 12, 10], the computational complexity of the graph based optimization can reach \( O(n^3) \) in the worst case, with \( n \) being the dimension of \( x \).

### 4 Unary Measurement Synchronization

#### 4.1 Unary Measurement Interpolation

It is clear from the previous section that a reduction in the number of states being estimated can both help with the overall computational complexity and the physical size of a graph during long term SLAM. Naively, if a new node is to be created at each sensor measurement time instance, the overall graph optimization frequency can suffer. To prolong high frequency graph optimization, in this section, we present our novel method of measurement alignment which allows for the estimation of the poses of a single sensor’s measurements.

![Figure 2: Given two measurements in the global frame of reference {1} and {2}, we interpolate to a new pose {i}. The above \( \lambda \) is the time-distance fraction that defines how much to interpolate the pose.](image)

Unary factors can appear when sensors measure information with respect to a single node. For example, GPS can provide global position measurements indirectly through latitude, longitude, and altitude readings, while LIDAR scan-matching to known maps can provide a direct reading of the global pose. Motivated to not add new graph nodes when receiving asynchronous data, we add a “corrected” measurement to an existing node by preforming pose interpolation between two sequential sensor measurements. Note that for GPS measurements we only need to perform 3D position interpolation, however for completeness we have derived the following interpolation for a 3D pose.
We define a time-distance fraction corresponding to the time-instance between two consecutive poses as follows:

\[ \lambda = \frac{(t_i - t_1)}{(t_2 - t_1)} \quad (3) \]

where \( t_1 \) and \( t_2 \) are the timestamps of the bounding measurements, and \( t_i \) is the desired interpolation time (i.e. the timestamp of the existing node). Under the assumption of a constant velocity motion model, we interpolate between the two pose readings:

\[
i_R R = \text{Expv} \left( \lambda \text{Logv}(\hat{R}_G) \right) \hat{R}_G
\]

\[ G_p = (1 - \lambda) G_p_1 + \lambda G_p_2 \quad (5) \]

where \( \{i_R, G_p\} \) is the interpolated measurement 3D pose and \( \{G_p_1, G_p_2\} \) are the bounding poses. While this interpolated measurement can now be directly added to the graph, the last step is to correctly compute the corresponding covariance needed in graph-based optimization. Taking the expectation of our error state \( \hat{z} = [\hat{G}_T G p_i] \) we can analytically derive the following covariance propagation:

\[
P_i = H_u P_{1,2} H_u^T = \left[ \begin{array}{c|c}
\delta_{\hat{G}_T} \delta_{\hat{G}_{p_1}} & 0_{3 \times 3} \\
\hline
0_{3 \times 3} & 0_{3 \times 3}
\end{array} \right] \left[ \begin{array}{c|c}
P_1 & 0_{6 \times 6} \\
0_{6 \times 6} & P_2 \end{array} \right] \left[ \begin{array}{c|c}
\delta_{\hat{G}_T} \delta_{\hat{G}_{p_1}} & 0_{3 \times 3} \\
\hline
0_{3 \times 3} & 0_{3 \times 3}
\end{array} \right] \quad (6)
\]

where \( P_{1,2} \) is the joint covariance matrix from the bounding poses, and \( \hat{\theta} \) and \( \hat{p} \) are the error states of each angle and position measurement, respectively. For detailed calculations of each Jacobian please see Appendix B. The resulting Jacobian matrix \( H_u \) is defined as the following:

\[
H_u = \left[ \begin{array}{c|c}
-\hat{R} J_r (\lambda \text{Logv}(\hat{R}_G)) & 0_{3 \times 3} \\
\hline
\lambda J_r^{-1} (\text{Logv}(\hat{R}_G)) - I & \hat{R} J_r (\lambda \text{Logv}(\hat{R}_G)) - I
\end{array} \right] \left[ \begin{array}{c|c|c}
0_{3 \times 3} & 0_{3 \times 3} & \lambda I \\
\hline
(1 - \lambda) I & 0_{3 \times 3} & 0_{3 \times 3}
\end{array} \right] \quad (7)
\]

where the Right Jacobian of \( SO(3) \) denoted as \( J_r (\phi) \) and its inverse \( J_r^{-1} (\phi) \) can both be found in Appendix A.

5 Relative Measurement Synchronization

Designing multi-sensor systems for state estimation often requires fusing asynchronous odometry readings from different sensor modules (e.g., ORB-SLAM2 [13] or LOAM [14]). A difficulty that arises is the unknown transformation between the different global frame of references of each module. This unknown comes from both the rigid transformation between sensors (which can be found through extrinsic calibration) and each module initializes its own global frame of reference independently. Rather than directly modifying the codebase of each module or performing sophisticated initialization, we combine the sequential odometry measurements into relative transforms; thereby, we remove the ambiguity of each module-to-module transformation.
5.1 Visual Relative Measurement

Given two poses in the second sensor’s global frame, \( \{ \overset{o}{o} R \overset{o}{p}_1 \} \) and \( \{ \overset{o}{o} R \overset{o}{p}_2 \} \) with the joint covariance \( P_{1,2} \), we calculate the relative transformation as follows:

\[
\overset{2}{R} = \overset{o}{R}_1^T \overset{o}{R} \\
\overset{0}{p}_2 = \overset{o}{R} (\overset{o}{p}_2 - \overset{o}{p}_1)
\]

where we define the unknown global frame of these 3D pose measurements as \( \{ o \} \) and their corresponding reference frames as \( \{ 1 \} \) and \( \{ 2 \} \). Next we can take the expected value of our error state \( \hat{\eta} = [\hat{\theta}^T \overset{o}{p}_1^T \hat{\theta}^T \overset{o}{p}_2^T]^T \) to analytically derive the corresponding covariance propagation:

\[
P_{12} = H_r P_{1,2} H_r^T =
\begin{bmatrix}
\delta^2 \theta & 0_{3 \times 3} & \delta^2 \theta & 0_{3 \times 3} \\
\delta^2 \theta & 0_{3 \times 3} & \delta^2 \theta & 0_{3 \times 3} \\
\delta^2 \theta & 0_{3 \times 3} & \delta^2 \theta & 0_{3 \times 3} \\
0_{6 \times 6} & P_1 & 0_{6 \times 6} & P_2
\end{bmatrix}
\begin{bmatrix}
\delta \theta & 0_{3 \times 3} & \delta \theta & 0_{3 \times 3} \\
\delta \theta & 0_{3 \times 3} & \delta \theta & 0_{3 \times 3} \\
\delta \theta & 0_{3 \times 3} & \delta \theta & 0_{3 \times 3} \\
0_{3 \times 3} & \delta \theta & 0_{3 \times 3} & \delta \theta
\end{bmatrix}
\]

(10)

where \( P_{1,2} \) is the joint covariance matrix from the global visual pose in the \( \{ o \} \) frame of reference. For detailed calculations of each Jacobian please see Appendix C. The resulting Jacobian matrix \( H_r \) is defined as the following:

\[
H_r =
\begin{bmatrix}
-\hat{\theta} R & 0_{3 \times 3} & \overset{o}{p}_1 \\
0_{3 \times 3} & I_{3 \times 3} & 0_{3 \times 3} \\
-\overset{o}{R}_1 & 0_{3 \times 3} & \overset{o}{R}_1
\end{bmatrix}
\]

(11)

5.2 Camera to Lidar Static Transformation

We now have the \( \{ \overset{L}{C}_1 R_1 p_{C2} \} \) relative transform between two camera poses with a corresponding covariance \( P_{12} \). Because the to be estimated graph nodes are lidar states this relative camera measurement needs to be transformed into the lidar frame of reference. This can be easily done as follows:

\[
\overset{L}{C}_1 R_1 = \overset{L}{C} R_1 \overset{C}{R}_1 \overset{L}{C} R_1^T \\
\overset{L}{C}_1 p_{L2} = \overset{L}{C} R_1 \left[ \overset{C}{C}_1 R_1^T p_{C2} + \overset{C}{R}_1 p_{C2} - \overset{C}{p}_L \right]
\]

(12)

(13)

where we define the lidar frame of reference as \( \{ Li \}, i \in \{ 1, 2 \} \) and the camera frame of reference as \( \{ Ci \}, i \in \{ 1, 2 \} \). It is assumed that the static transform, \( \{ \overset{L}{C}_1 R_1 p_{C2} \} \), from the lidar to camera frame of reference are known from offline calibration. Given the above transform, special care needs to be taken to calculate the relative covariance matrix in the lidar frame of reference. We can take the expected value of our error state \( \hat{\eta} = [\overset{C}{C}_1 \hat{\theta}^T \overset{C}{p}_{C2}^T]^T \) to compute the corresponding covariance.

\[
P_{L12} = H_s P_{C12} H_s^T =
\begin{bmatrix}
\delta^2 \theta & 0_{3 \times 3} \\
\delta^2 \theta & 0_{3 \times 3} \\
\delta^2 \theta & 0_{3 \times 3} \\
0_{6 \times 6} & P_{C12}
\end{bmatrix}
\begin{bmatrix}
\delta \theta & 0_{3 \times 3} \\
\delta \theta & 0_{3 \times 3} \\
\delta \theta & 0_{3 \times 3} \\
0_{3 \times 3} & \delta \theta
\end{bmatrix}
\]

(14)

where \( P_{C12} \) is the relative camera covariance calculated in Section 5.1. For detailed calculations of each Jacobian please see Appendix D. The resulting Jacobian matrix \( H_s \) is defined as the following:

\[
H_s =
\begin{bmatrix}
\overset{L}{C} R & 0_{3 \times 3} \\
-\overset{L}{C} R & \overset{C}{C}_1 \overset{L}{R}_1 [\overset{C}{C}_1 p_{C2}]\overset{L}{C} R
\end{bmatrix}
\]

(15)
5.3 Relative Measurement Interpolated

Figure 3: Given a relative transformation, calculated using (12) and (13), between the \{1\} and \{2\} frame of reference, we extrapolate this relative transformation to the desired beginning \{b\} and end \{e\} poses. The above λs are the time-distance fractions that we use to extrapolate the relative transformation.

We now have the \{2\}_1 R, 1_p_2 \} relative transform between two poses in the correct frame of reference and a corresponding covariance \( P_{12} \). Due to the asynchronous nature of the measurements from two different sensors, the times corresponding to the beginning and end of the relative transformation will not align with matched existing state poses. Therefore, under the assumption of a constant velocity motion, we extrapolate the relative transformation across the desired interval. This intuitively corresponds to a “stretching” of the relative pose measurement in time. We define two time-distance fractions that determine how much the relative transformation needs to be extended (see Figure 3):

\[
\lambda_b = \frac{t_1 - t_b}{t_2 - t_1} \quad \lambda_e = \frac{t_e - t_2}{t_2 - t_1}
\]  

The λ’s describe the magnitude that the relative transformation is to be “stretched” in each direction, with the subscripts \( b \) and \( e \) denoting the beginning and end state poses. These time-distance fractions can also be negative, corresponding to the “shrinking” of the relative transformation. Given the relative transform and the time-distance fractions, we define the following extrapolation equations:

\[
^{b}R = \text{Expv} \left[ (1 + \lambda_b + \lambda_e) \text{Logv} \left( \hat{2}_1 R \right) \right]
\]  

\[
^{b}p_e = (1 + \lambda_b + \lambda_e) \text{Expv} \left[ -\lambda_b \text{Logv} \left( \hat{2}_1 R \right) \right] 1_p_2
\]  

The covariance propagation is then given by:

\[
P_{be} = H_i P_{12} H_i^T = \begin{bmatrix}
\delta^b_\theta \\
\delta^e_\theta \\
\delta^b_\rho_e \\
\delta^e_\rho_e
\end{bmatrix}
\begin{bmatrix}
0_{3\times3} \quad 0_{3\times3}
\end{bmatrix}
\begin{bmatrix}
\delta^b_\theta \\
\delta^e_\theta \\
\delta^b_\rho_e \\
\delta^e_\rho_e
\end{bmatrix}
\]  

where \( P_{12} \) is the transformed relative covariance calculated in Section 5.2. For detailed calculations of each Jacobian please see Appendix E. The resulting Jacobian matrix \( H_i \) is defined as the following:

\[
H_i = \begin{bmatrix}
J_r \left[ (1 + \lambda_b + \lambda_e) \text{Logv}(\hat{2}_1 R^T) \right] (1 + \lambda_b + \lambda_e) J_r^{-1} \left[ \text{Logv}(\hat{2}_1 R^T) \right] \\
(1 + \lambda_b + \lambda_e) \text{Expv} \left[ \lambda_b \text{Logv}(\hat{2}_1 R^T) \right] \\
[1_p_2 \times] J_r (\lambda_b \text{Logv}(\hat{2}_1 R^T)) \lambda_b J_r^{-1} (\text{Logv}(\hat{2}_1 R^T)) \\
(1 + \lambda_b + \lambda_e) \text{Expv} \left[ -\lambda_b \text{Logv}(\hat{2}_1 R) \right]
\end{bmatrix}
\]
6 System Design

6.1 Design Motivations

The proposed method allows for the reduction of the overall graph complexity during asynchronous sensor fusion. We now propose a system that leverages the use of asynchronous sensors in the application of autonomous driving. To both facilitate the flexibility of the vehicle design and reduce cost, we aim to run the system on a vehicle without access to a GPS unit and with low cost asynchronous sensors (i.e., without the use of electronic triggering). This design constraint presents the unique challenge of still needing to localize the vehicle in the GPS frame of reference without the use of a traditional GPS sensor. By publishing the vehicle state estimate in the GPS frame of reference, we allow for existing global path planning and routing modules to continue to work as expected. To overcome this challenge, we present a unique prior LIDAR map that allows for the vehicle to both initialize and localize in the GPS frame of reference. Specifically we design a framework with two separate sub-systems as follows:

1. Creation of an accurate prior map using a vehicle that has an additional Real Time Kinematic (RTK) GPS sensor unit.

2. GPS-denied localization leveraging the prior map to localize in the GPS frame of reference.

This framework is flexible and cost effective as only a single “collection” vehicle is needed to build the prior map that multiple lower cost vehicles can leverage. Specifically, this prior map allows for localization in the GPS frame of reference without the use of GPS measurements during runtime and can support localization in GPS-denied environments (e.g., tunnels or parking garages). Both sub-systems can leverage the proposed asynchronous factor interpolation to enable the use of low cost asynchronous sensors while ensuring a reduction of overall graph complexity.

6.2 System Overview - Prior Map

The first sub-system we propose is one that generates an accurate prior map that can be leveraged by the second sub-system to localize in the GPS frame of reference. Shown in Figure 4, we fuse odometry measurements from openly available stereo and LIDAR modules, ORB-SLAM2 [13] and LOAM [14], respectively, with a RTK GPS unit. Both of these modules provide six degree of freedom pose estimates.

Note that both modules do not normally provide a corresponding covariance needed for batch optimization. We reference the reader to the appendices G and F for details on how we computed these covariances. We run LOAM in the default mode, while ORB-SLAM2 is run first in “mapping”
mode to generate a map of the environment. We then use ORB-SLAM2 in “localization” mode to limit jumps due to loop closures. One could run ORB-SLAM2 in either mode, but since a prior visual map can be created using the same dataset used to generate the LIDAR prior cloud we can leverage this to provide additional information. We also note that both odometry modules must provide “to-scale” information. We found that ORB-SLAM2 is susceptible to small errors in the stereo calibration and could cause emitted global poses to not be “to-scale”.

We estimate LIDAR states connected with consecutive non-interpolated binary factors from LOAM LIDAR odometry. To provide additional robustness and information into the graph, we connect consecutive states with interpolated binary factors (Section 5) from ORB-SLAM2 visual odometry. To ensure that the estimated states are in the GPS frame of reference, we attach interpolated unary factors (Section 4) from the RTK GPS sensor. Both ORB-SLAM2 visual binary factors and RTK GPS unary factors need to be interpolated because both sensors are asynchronous to the LIDAR sensor.

The graph can be solved in real-time using an incremental solver such as iSAM2 [12] or offline with a full batch solver. It is then simple to construct a prior map using the estimated states and their corresponding LIDAR point clouds. To evaluate the overall quality of the generated prior map point cloud, the cloud is visually inspected for misalignment on environmental planes such as walls or exterior of buildings. The generated prior map from the experimental dataset can be see in Figure 5.

![Figure 5: Prior map generated from the experimental dataset.](image)

### 6.3 System Overview - GPS-Denied Localization

Using the generated prior map, localization in the GPS frame can be performed without the use of a GPS sensor. As seen in Figure 4, we estimate LIDAR states that are connected with non-interpolated and interpolated binary factors (Section 5) from LOAM and ORB-SLAM2 odometry modules, respectively. In addition to these two binary factors, we perform Iterative Closest Point (ICP) matching between the newest LIDAR point cloud to the generated prior map. This ICP transform can then be added as a non-interpolated unary factor into the factor graph. These unary factors constrain the graph to be in the GPS frame of reference during 3D pose estimation.
To provide real-time localization capabilities, we leverage the iSAM2 solver during GPS-denied state estimation. The estimation operates at the frequency of the LIDAR sensor limited only by the speed the LOAM module can process measurements. It was found that when creating a unary factor using ICP matching to the prior map took upwards of 1-2 seconds. To overcome this long computation time, incoming LIDAR clouds are processed at a lower frequency in a secondary thread, and then added to the graph after successful ICP matching.

7 Experiential Results

7.1 System Validation

To access the overall performance of the GPS denied system, we constructed a data collection vehicle with both a combination of low cost sensors and a RTK GPS sensor. The vehicle is equipped with a 8 channel Quanergy M8 LIDAR [15], ZED stereo camera [16], and RTK enabled NovAtel Propak6 GPS sensor [17]. The Quanergy M8 LIDAR was run at 10Hz, while the ZED stereo camera was run at 30Hz with a resolution of 672 by 376. The RTK enabled NovAtel Propak6 GPS sensor operated at 20Hz with an average accuracy of ±15 centimeters. The GPS solution accuracy allows for the creation of a high quality prior map (see Figure 5). To facilitate the GPS denied system, a dataset was first collected on the vehicle and then processed using a full batch solver. Following the proposed procedure in Section 6.2, LIDAR factors are added to the factor graph, while both stereo and GPS factors are interpolated and then directly connected to corresponding LIDAR states. The resulting LIDAR point cloud, created in the GPS frame of reference, can then be used during GPS denied navigation.

To represent the real world, the GPS denied system was tested on the day following the data collection for the prior map. This was to introduce changes in the environment, such as changes in car placement and shrubbery, while also showing that the prior map can still be leveraged. The same vehicle was used with the only difference being that the RTK GPS was not used in the GPS denied localization. This RTK GPS was instead used to provide an accurate ground truth comparison. Following the proposed procedure in Section 6.3, incoming LIDAR point clouds are matched to the map generated the previous day and then added to the factor graph after successful ICP alignment.
Figure 6: Position of the vehicle over the 10 runs. Vehicle starts in the top right corner and drives around the circle.

Figure 7: Average position error in the x,y,z over 10 runs. GPS denied estimation compared at each time instance, of the 500 meter long run, with the RTK GPS position. Average vehicle speed of 6mph.

Figure 8: Average position error magnitude over 10 runs. GPS denied estimation compared at each time instance, of the 500 meter long run, with the RTK GPS position. Average vehicle speed of 6mph.
The estimated vehicle state is compared to the corresponding output of the RTK GPS. As seen in Figure 8, when performing GPS denied localization, the system was able to remain within a stable 2 meter accuracy. We compared the proposed factor interpolation method against a naive approach of factor addition into the graph which ignores the issue of time delay and directly attaches incoming factors to the closest nodes without interpolation. The average RMSE was 0.71 meters for the proposed method and 0.93 meters for the naive approach (overall 23.6% decrease).

7.2 Evaluating the Asynchronous Measurement Alignment

Having shown that the system is able to accurately localize in real-time without the use of GPS, we next evaluated how the interpolation impacts the estimation. To do so, we did not use the ICP matching to the LIDAR prior cloud and instead only used the pure odometry from LOAM and ORB-SLAM2.

![Comparison of the proposed method and naive approach position over 10 runs. Vehicle starts in the top right corner and drives around the circle.](image)

Figure 9: Comparison of the proposed method and naive approach position over 10 runs. Vehicle starts in the top right corner and drives around the circle.
Figure 10: Comparison of the proposed method and naive approach, over 10 runs, using pure odometry measurements.

Figure 11: Comparison of the proposed method and naive approach, over 10 runs, using pure odometry measurements.

Seen in Figure 11, the proposed factor interpolation outperformed the estimation accuracy of the naive approach. The RMSE of the naive approach was 26.74 meters and the proposed method’s average error was 7.026 meters (overall 73.7% decrease). This shows that the use of interpolation on incoming binary factors can greatly increase the estimation accuracy, without increasing graph complexity.

8 Conclusions and Future Work

In this paper, we have developed a general approach of asynchronous measurement alignment within the graph-based optimization framework of mapping and localization in order for optimal fusion of multimodal sensors. The designed framework provides a modular system with the ability to replace individual modules and allow for any sensor to be incorporated. The system has been tested on an experimental dataset and compared to a naive approach to show the improvement due to the proposed asynchronous measurement alignment. Looking forward, we will incorporate other sensors, such as Inertial Measurement Units (IMUs), through the use of analytically IMU preintegration developed in our prior work [18] to improve the system fault tolerance, if the main sensor fails. We will also investigate how to improve the current mapping and localization, in particular, when autonomously driving in dynamic urban environments.

A.1: Skew Symmetric Matrices

\[
\begin{align*}
\begin{bmatrix}
\cdot \\
\times
\end{bmatrix} : \mathbb{R}^3 & \to S^3_x \\
[v \times] & = [v \times]
\end{align*}
\]

(20)

Given a rotation matrix \( R \in SO(3) \) we can perform the following:

\[
R [v \times] R^\top = [Rv \times]
\]

(21)

Given two vectors \( v, p \in \mathbb{R}^3 \) we can perform the following:

\[-[v \times] p = [p \times] v
\]

(22)

A.2: Matrix Exponential

\[
\begin{align*}
\text{Exp: } S^3_x & \to SO(3) \\
\text{Exp}\left([G \theta \times]\right) & = \hat{G} R
\end{align*}
\]

(23)

\[
\begin{align*}
\text{Expv: } \mathbb{R}^3 & \to SO(3) \\
\text{Expv}(G \theta) & = \hat{G} R
\end{align*}
\]

(24)

A.3: Matrix Logarithm

\[
\begin{align*}
\text{Log: } SO(3) & \to S^3_x \\
\text{Log}(\hat{G} R) & = [\hat{G} \theta \times]
\end{align*}
\]

(25)

\[
\begin{align*}
\text{Logv: } SO(3) & \to \mathbb{R}^3 \\
\text{Logv}(\hat{G} R) & = \hat{G} \theta
\end{align*}
\]

(26)

A.4: First-order Approximation

Given some small value \( \delta \theta \) we can apply the following approximation:

\[
\text{Expv}(\phi + \delta \theta) \approx \text{Expv}(\phi) \text{Expv}(J_r(\phi) \delta \theta)
\]

(27)

First-order approximation for small angles with Logarithm applied:

\[
\text{Logv}(\text{Expv}(\phi) \text{Expv}(\delta \theta)) \approx \phi + J_r^{-1}(\phi) \delta \theta
\]

(28)

A.5: Small Angle

\[
\text{Exp}([\delta \theta \times]) \approx \mathbf{I} + [\delta \theta \times]
\]

(29)
A.6: Right Jacobian

The Right Jacobian of $SO(3)$ $J_r(\phi)$ is defined by [19, 20]:

$$J_r(\phi) = I - \frac{1 - cos(\|\phi\|)}{\|\phi\|^2} [\phi \times] + \frac{\|\phi\| - sin(\|\phi\|)}{\|\phi\|^3} [\phi \times]^2$$  \hspace{1cm} (30)

The Right Jacobian inverse of $SO(3)$ $J_r^{-1}(\phi)$ is defined by [19, 20]:

$$J_r^{-1}(\phi) = I + \frac{1}{2} [\phi \times] + \left(\frac{1}{\|\phi\|^2} - \frac{1}{2} \frac{1 + cos(\|\phi\|)}{\|\phi\| sin(\|\phi\|)} \right) [\phi \times]^2$$  \hspace{1cm} (31)
Appendix B: Jacobians for Unary Measurement

B.1: $\frac{\delta_i G}{\delta_i \theta}$ Jacobian Derivation

To find $\frac{\delta_i G}{\delta_i \theta}$ we perturb the measurement function by a error angle $\frac{1}{G}\theta$ and define $\frac{1}{G}R \approx \text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R$

to get the following:

$$\text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R = \text{Expv} \left[ \lambda \ \text{Logv} \left( \frac{2}{G}\hat{R} \left( \text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R \right)^T \right) \right] \text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R$$

$$= \text{Expv} \left[ \lambda \ \text{Logv} \left( \frac{2}{G}\hat{R} \frac{1}{G}R^T \text{Expv}(\frac{1}{G}\theta) \right) \right] \text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R$$

$$= \text{Expv} \left[ \lambda \ \text{Logv} \left( \frac{2}{G}\hat{R} \text{Expv}(\frac{1}{G}\theta) \right) \right] \text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R$$

By applying Equation 28 and defining $\text{Logv}(\frac{1}{G}\hat{R}) = \hat{\phi}$ we get:

$$\approx \text{Expv} \left[ \lambda \ \hat{\phi} + \lambda \ J^{-1}(\hat{\phi})\frac{1}{G}\theta \right] \text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R$$

Applying Equation 27 we get:

$$\approx \text{Expv} \left( \lambda \ \hat{\phi} \right) \text{Expv} \left( J_r(\lambda \ \hat{\phi}) \lambda \ J^{-1}(\hat{\phi})\frac{1}{G}\theta \right) \text{Expv}(-\frac{1}{G}\theta)\frac{1}{G}R$$

Next we use our small angle approximation, Equation 29, and by removing all error squared terms, we get the following:

$$\approx \frac{1}{G}\hat{R} \left( I + \left[ J_r(\lambda \ \hat{\phi}) \lambda \ J^{-1}(\hat{\phi})\frac{1}{G}\theta \times \right] \left( I + \left[ \frac{1}{G}\theta \times \right] \right) \frac{1}{G}\hat{R}$$

$$\approx \frac{1}{G}\hat{R} \left( I + \left[ J_r(\lambda \ \hat{\phi}) \lambda \ J^{-1}(\hat{\phi})\frac{1}{G}\theta \times \right] \left( I + \left[ \frac{1}{G}\theta \times \right] \right) \frac{1}{G}\hat{R}$$

Applying the $R [v \times] R^T = [Rv \times]$ property of skew symmetric matrices, we can perform the following:

$$\approx \frac{1}{G}\hat{R} \left( I + \left[ \ldots \right] \frac{1}{G}\theta \times \right) \frac{1}{G}\hat{R}$$

$$\approx \frac{1}{G}\hat{R} + \frac{1}{G}\hat{R} \left[ \ldots \right] \frac{1}{G}\theta \times \frac{1}{G}\hat{R}$$

$$\approx \frac{1}{G}\hat{R} + \frac{1}{G}\hat{R} \left[ \ldots \right] \frac{1}{G}\theta \times \frac{1}{G}\hat{R}$$

$$\approx \frac{1}{G}\hat{R} + \frac{1}{G}\hat{R} \left[ \ldots \right] \frac{1}{G}\theta \times \frac{1}{G}\hat{R}$$

$$\approx \frac{1}{G}\hat{R} + \frac{1}{G}\hat{R} \left[ J_r(\lambda \ \hat{\phi}) \lambda \ J^{-1}(\hat{\phi}) - I \right] \frac{1}{G}\theta \times \frac{1}{G}\hat{R}$$

$$\approx \text{Expv} \left( \frac{1}{G}\hat{R} \left[ J_r(\lambda \ \hat{\phi}) \lambda \ J^{-1}(\hat{\phi}) - I \right] \frac{1}{G}\theta \times \right) \frac{1}{G}\hat{R}$$

Thus, we have the following:

$$\frac{\delta_i G}{\delta_i \theta} = -\frac{1}{G}\hat{R} \left( J_r(\lambda \ \text{Logv}(\frac{1}{G}\hat{R})) \lambda \ J^{-1}(\text{Logv}(\frac{1}{G}\hat{R})) - I \right)$$

RPNG-2017-ASYNC
B.2: $\frac{\delta_i \hat{\theta}}{\delta_i G \hat{\theta}}$ Jacobian Derivation

To find $\frac{\delta_i \hat{\theta}}{\delta_i G \hat{\theta}}$, we perturb the measurement function by an error angle $\frac{\delta_i}{2} \hat{\theta}$ and define $\frac{\delta_i}{2} R \approx \text{Expv}(-\frac{\delta_i}{2} \hat{\theta}) \frac{\delta_i}{2} R$ to get the following:

$$\text{Expv}(-\frac{\delta_i}{2} \hat{\theta}) \frac{\delta_i}{2} R = \text{Expv} \left[ \lambda \ \text{Logv} \left( \text{Expv}(-\frac{\delta_i}{2} \hat{\theta}) \frac{\delta_i}{2} R \frac{i}{2} R^\top \right) \right] \frac{\delta_i}{2} R \quad (46)$$

$$= \text{Expv} \left[ -\lambda \ \text{Logv} \left( \frac{i}{2} R^\top \ \text{Expv}(\frac{\delta_i}{2} \hat{\theta}) \right) \right] \frac{\delta_i}{2} R \quad (47)$$

By applying Equation 28 and defining $\text{Logv}(\frac{i}{2} R^\top) = \frac{\lambda}{2} \phi$ we get:

$$\approx \text{Expv} \left[ -\lambda \ \frac{\lambda}{2} \phi - \lambda \ J_r^{-1}(\frac{i}{2} \phi) \frac{\delta_i}{2} \hat{\theta} \right] \frac{\delta_i}{2} R \quad (48)$$

Applying Equation 27 we get:

$$\approx \text{Expv} \left( -\lambda \ \frac{\lambda}{2} \phi \right) \text{Expv} \left( -J_r(\lambda \ \frac{\lambda}{2} \phi) \lambda \ J_r^{-1}(\frac{i}{2} \phi) \frac{\delta_i}{2} \hat{\theta} \right) \frac{\delta_i}{2} R \quad (49)$$

Next we use our small angle approximation, Equation 29, to get the following:

$$\approx \frac{i}{2} \hat{R} \left( I + \left[ -J_r(\frac{i}{2} \phi) \lambda \ J_r^{-1}(\frac{i}{2} \phi) \frac{i}{2} \hat{\theta} \times \right] \right) \frac{\delta_i}{2} R \quad (50)$$

Applying the $R [v \times] R^\top = [Rv \times]$ property of skew symmetric matrices, we can perform the following:

$$\approx \frac{i}{2} \hat{R} \left( I + \left[ \ldots \right] \frac{i}{2} \hat{\theta} \times \right) \frac{\delta_i}{2} R \quad (51)$$

$$\approx \frac{i}{2} \hat{R} \frac{i}{2} \hat{R} + \frac{i}{2} \hat{R} \left[ \ldots \right] \frac{i}{2} \hat{\theta} \times \frac{\delta_i}{2} R \quad (52)$$

$$\approx \frac{i}{2} \hat{R} + [\ldots] \frac{i}{2} \hat{\theta} \times \frac{\delta_i}{2} R \quad (53)$$

$$\approx \frac{i}{2} \hat{R} + \frac{i}{2} \hat{R} \left[ \ldots \right] \frac{i}{2} \hat{\theta} \times \frac{\delta_i}{2} R \quad (54)$$

$$\approx \frac{i}{2} \hat{R} + \left[ \frac{i}{2} \hat{R} \right] \frac{i}{2} \hat{\theta} \times \frac{\delta_i}{2} R \quad (55)$$

$$\approx \text{Expv} \left(-\frac{i}{2} \hat{R} J_r(\lambda \ \frac{\lambda}{2} \phi) \lambda \ J_r^{-1}(\frac{i}{2} \phi) \frac{\delta_i}{2} \hat{\theta} \times \right) \frac{\delta_i}{2} R \quad (56)$$

Thus, we have the following:

$$\frac{\delta_i \hat{\theta}}{\delta_i G \hat{\theta}} = \frac{i}{2} \hat{R} J_r(\lambda \ \text{Logv}(\frac{i}{2} R^\top)) \lambda \ J_r^{-1}(\text{Logv}(\frac{i}{2} R^\top)) \quad (57)$$

B.3: $\frac{\delta G \hat{p}_i}{\delta G \hat{p}_1}$ Jacobian Derivation

To find $\frac{\delta G \hat{p}_i}{\delta G \hat{p}_1}$, we perturb the measurement function by an error value of $G \hat{p}_1$.

$$G \hat{p}_i + G \hat{p}_i = (1 - \lambda)(G \hat{p}_1 + G \hat{p}_1) + \lambda G \hat{p}_2 \quad (58)$$

$$= (1 - \lambda)G \hat{p}_1 + \lambda G \hat{p}_2 + (1 - \lambda)G \hat{p}_1 \quad (59)$$

Thus, we have the following:

$$\frac{\delta G \hat{p}_i}{\delta G \hat{p}_1} = (1 - \lambda) \quad (60)$$

RPNG-2017-ASYNC 18
B.4: $\frac{\delta G\hat{p}_1}{\delta G\hat{p}_2}$ Jacobian Derivation

To find $\frac{\delta G\hat{p}_1}{\delta G\hat{p}_2}$ we perturb the measurement function by an error value of $G\hat{p}_2$.

\[ G\hat{p}_i + G\hat{p}_2 = (1 - \lambda)G\hat{p}_1 + \lambda(G\hat{p}_2 + G\hat{p}_2) \]
\[ = (1 - \lambda)G\hat{p}_1 + \lambda G\hat{p}_2 + \lambda G\hat{p}_2 \]

Thus, we have the following:

\[
\begin{align*}
\frac{\delta G\hat{p}_1}{\delta G\hat{p}_2} &= \lambda 
\end{align*}
\]
Appendix C: Jacobians for Relative Transformation

C.1: $\frac{\delta^2 \theta}{\delta \hat{\theta}^2}$ Jacobian Derivation

To find $\frac{\delta^2 \theta}{\delta \hat{\theta}^2}$ we perturb the measurement function by an error angle $\hat{\theta}$ and define $\hat{\theta}$ to get the following:

$$
\left( I - [\hat{\theta} \times] \right) \hat{\theta} = \hat{\theta} \left( I - [\hat{\theta} \times] \right)^\top \hat{\theta}
$$

(66)

$$
= \hat{\theta} \hat{\theta}^\top \left( I + [\hat{\theta} \times] \right)
$$

(67)

$$
= \hat{\theta} \hat{\theta}^\top \left( I - [\hat{\theta} \times] \right)
$$

(68)

Applying the $R [v \times] R^\top = [Rv \times]$ property of skew symmetric matrices, we can perform the following:

$$
= \hat{\theta} \hat{\theta}^\top + \hat{\theta} \hat{\theta}^\top \hat{\theta} \hat{\theta}^\top \hat{\theta} \hat{\theta}^\top
$$

(69)

$$
= \hat{\theta} \hat{\theta}^\top + \hat{\theta} \hat{\theta}^\top \hat{\theta} \hat{\theta}^\top
$$

(70)

$$
= \left( I - [-\hat{\theta} \hat{\theta} \times] \right) \hat{\theta} \hat{\theta}^\top
$$

(71)

Thus, we have the following:

$$
\frac{\delta^2 \theta}{\delta \hat{\theta}^2} = -\hat{\theta}
$$

(72)

C.2: $\frac{\delta^2 \hat{\theta}}{\delta \hat{\theta}^2}$ Jacobian Derivation

To find $\frac{\delta^2 \hat{\theta}}{\delta \hat{\theta}^2}$ we perturb the measurement function by an error angle $\hat{\theta}$ and define $\hat{\theta}$ to get the following:

$$
\left( I - [\hat{\theta} \times] \right) \hat{\theta} = \left( I - [\hat{\theta} \times] \right)^\top \hat{\theta}
$$

(73)

$$
= \left( I - [\hat{\theta} \times] \right)^\top \hat{\theta}
$$

(74)

Thus, we have the following:

$$
\frac{\delta^2 \hat{\theta}}{\delta \hat{\theta}^2} = I_{3 \times 3}
$$

(75)

C.3: $\frac{\delta \bar{p}_2}{\delta \hat{\theta}}$ Jacobian Derivation

To find $\frac{\delta \bar{p}_2}{\delta \hat{\theta}}$ we perturb the measurement function by an error angle $\hat{\theta}$ and define $\hat{\theta}$ to get the following:

$$
\bar{p}_2 + \hat{\theta} = \left( I - [\hat{\theta} \times] \right) \hat{\theta}
$$

(76)

$$
= \hat{\theta} - [\hat{\theta} \times] \hat{\theta}
$$

(77)
Applying the \(- [v \times] p = [p \times] v\) property of skew symmetric matrices, we can perform the following:

\[
\frac{\delta^1 \hat{p}_2}{\delta^1 \theta} = [\hat{o}_p (\hat{o} \hat{p}_2 - \hat{o} \hat{p}_1) \times]^{1} \hat{o}_p
\]  

(78)

Thus, we have the following:

\[
\frac{\delta^1 \hat{p}_2}{\delta^j \theta} = [\hat{o}_p (\hat{o} \hat{p}_2 - \hat{o} \hat{p}_1) \times]^{j} \hat{o}_p
\]  

(79)

C.4: \(\frac{\delta^1 \hat{p}_2}{\delta^0 \hat{p}_1}\) Jacobian Derivation

To find \(\frac{\delta^1 \hat{p}_2}{\delta^0 \hat{p}_1}\) we perturb the measurement function by a error value of \(\hat{o} \hat{p}_1\).

\[
1^p_2 + \hat{p}_2 = \hat{o}_p (\hat{o} \hat{p}_2 - \hat{o} \hat{p}_1 - \hat{o} \hat{p}_1) = \hat{o}_p (\hat{o} \hat{p}_2 - \hat{o} \hat{p}_1) - \hat{o}_p \hat{o} \hat{p}_1
\]  

(80)

(81)

Thus, we have the following:

\[
\frac{\delta^1 \hat{p}_2}{\delta^0 \hat{p}_1} = -\hat{o}_p
\]  

(83)

C.5: \(\frac{\delta^1 \hat{p}_2}{\delta^0 \hat{p}_2}\) Jacobian Derivation

To find \(\frac{\delta^1 \hat{p}_2}{\delta^0 \hat{p}_2}\) we perturb the measurement function by a error value of \(\hat{o} \hat{p}_2\).

\[
1^p_2 + \hat{p}_2 = \hat{o}_p (\hat{o} \hat{p}_2 + \hat{o} \hat{p}_2 - \hat{o} \hat{p}_1) = \hat{o}_p (\hat{o} \hat{p}_2 - \hat{o} \hat{p}_1) + \hat{o}_p \hat{o} \hat{p}_2
\]  

(84)

(85)

Thus, we have the following:

\[
\frac{\delta^1 \hat{p}_2}{\delta^0 \hat{p}_2} = \hat{o}_p
\]  

(87)
Appendix D: Jacobians for Lidar to Camera Static Transformation

D.1: \( \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} \) Jacobian Derivation

To find \( \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} \) we perturb the measurement function by a error angle \( C_1^2\hat{\theta} \) and define \( \frac{1}{R} \approx \begin{pmatrix} I & -[C_1^2\hat{\theta} \times] \end{pmatrix} C_1^2 \hat{R} \) to get the following:

\[
\begin{align*}
\left( I - [L^2_{\hat{\theta}} \hat{\theta} \times] \right) \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} &= L_C^2 \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} \begin{pmatrix} I & -[C_1^2\hat{\theta} \times] \end{pmatrix} C_1^2 \hat{R} L_C^2 R^T \\
&= \frac{L^2_{\hat{\theta}}}{L^2_{\hat{\theta}}} \hat{R} - L_C^2 \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} [C_1^2\hat{\theta} \times] \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} R^T \\
&= \frac{L^2_{\hat{\theta}}}{L^2_{\hat{\theta}}} \hat{R} - L_C^2 \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} [C_1^2\hat{\theta} \times] \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} R^T L_C^2 \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} R^T \quad \text{(88)} \end{align*}
\]

Applying the \( R [v \times] R^T = [Rv \times] \) property of skew symmetric matrices, we can perform the following:

\[
\begin{align*}
&= \frac{L^2_{\hat{\theta}}}{L^2_{\hat{\theta}}} \hat{R} - [L_C^2 \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} [C_1^2\hat{\theta} \times]] \frac{L^2_{\hat{\theta}}}{L^2_{\hat{\theta}}} \hat{R} \\
&= \left( I - L_C^2 \frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} [C_1^2\hat{\theta} \times] \right) \frac{L^2_{\hat{\theta}}}{L^2_{\hat{\theta}}} \hat{R} \quad \text{(91)}
\end{align*}
\]

Thus, we have the following:

\[
\frac{L^2_{\hat{\theta}}}{C_1^2\hat{\theta}} = L_C^2 \hat{R} \quad \text{(92)}
\]

D.2: \( \frac{L^1_{\hat{\theta}}}{C_1^2\hat{\theta}} \) Jacobian Derivation

To find \( \frac{L^1_{\hat{\theta}}}{C_1^2\hat{\theta}} \) we perturb the measurement function by a error angle \( C_1^2\hat{\theta} \) and define \( \frac{1}{R} \approx \begin{pmatrix} I & -[C_1^2\hat{\theta} \times] \end{pmatrix} C_1^2 \hat{R} \) to get the following:

\[
\begin{align*}
L^1_{\hat{p}_L} + L^1_{\hat{p}_L} &= L_C^2 \left( \begin{pmatrix} I & -[C_1^2\hat{\theta} \times] \end{pmatrix} C_1^2 \hat{R} \right)^T C_p^L + C_1^2 \hat{p}_{C_2} - C_p^L \quad \text{(94)} \\
&= L_C^2 \left( C_1^2 \hat{R}^T \begin{pmatrix} I & -[C_1^2\hat{\theta} \times] \end{pmatrix} \right) C_p^L + C_1^2 \hat{p}_{C_2} - C_p^L \quad \text{(95)} \\
&= L^1_{\hat{p}_L} + L_C^2 \left( C_1^2 \hat{R}^T \begin{pmatrix} C_1^2\hat{\theta} \times \end{pmatrix} \right) C_p^L \quad \text{(96)}
\end{align*}
\]

Applying the \( -[v \times] p = [p \times] v \) property of skew symmetric matrices, we can perform the following:

\[
\begin{align*}
&= L^1_{\hat{p}_L} - L_C^2 \left( C_1^2 \hat{R}^T \begin{pmatrix} C_p^L \times \end{pmatrix} \right) \hat{C}_1^2\hat{\theta} \quad \text{(97)}
\end{align*}
\]

Thus, we have the following:

\[
\frac{L^1_{\hat{p}_L}}{C_1^2\hat{\theta}} = -L_C^2 \left( C_1^2 \hat{R}^T \begin{pmatrix} C_p^L \times \end{pmatrix} \right) \quad \text{(98)}
\]
D.3: \( \frac{L_1 \hat{p}_{L2}}{C_1 \hat{p}_{C2}} \) Jacobian Derivation

To find \( \frac{L_1 \hat{p}_{L2}}{C_1 \hat{p}_{C2}} \) we perturb the measurement function by a error value of \( C_1 \hat{p}_{C2} \).

\[
L_1 \hat{p}_{L2} + L_1 \hat{p}_{L2} = L C R \left( C_1 \hat{R^T} C p_L + C_1 \hat{p}_{C2} + C_1 \hat{p}_{C2} - C p_L \right)
\]

\[
= L_1 \hat{p}_{L2} + L C R C_1 \hat{p}_{C2} \quad (100)
\]

Thus, we have the following:

\[
\frac{L_1 \hat{p}_{L2}}{C_1 \hat{p}_{C2}} = L C R \quad (103)
\]
Appendix E: Jacobians for Relative Measurement Interpolation

E.1: $\frac{\delta}{\delta_i \theta}$ Jacobian Derivation

To find $\frac{\delta}{\delta_i \theta}$ we perturb the measurement function by a error angle $\frac{2}{1} \tilde{\theta}$ and define $\frac{1}{2} \mathbf{R} \approx \text{Expv}(\frac{-2}{1} \tilde{\theta})^2 \hat{\mathbf{R}}$.

$$\text{Expv}(\frac{-2}{1} \tilde{\theta})^2 \hat{\mathbf{R}} = \text{Expv} \left[ (1 + \lambda_b + \lambda_e) \text{Logv} \left( \text{Expv}(\frac{-2}{1} \tilde{\theta})^2 \hat{\mathbf{R}} \right) \right] \approx \text{Expv} \left[ (1 + \lambda_b + \lambda_e) \frac{1}{2} \mathbf{R} \text{Expv}((\frac{2}{1} \tilde{\theta})) \right]$$

By applying Equation 28 and defining $\text{Logv}((\frac{2}{1} \tilde{\theta})) \approx \frac{1}{2} \phi$ we get:

$$\approx \text{Expv} \left[ - (1 + \lambda_b + \lambda_e) \left( \frac{1}{2} \phi + J_r^{-1}(\frac{1}{2} \phi)^2 \tilde{\theta} \right) \right]$$

By taking the transpose and applying Equation 27 we get:

$$\frac{2}{1} \tilde{\theta} \text{Expv}(\frac{2}{1} \tilde{\theta}) \approx \text{Expv}(\frac{1}{2} \mathbf{R}) \approx \text{Expv} \left[ (1 + \lambda_b + \lambda_e) \left( \frac{1}{2} \phi + J_r^{-1}(\frac{1}{2} \phi)^2 \tilde{\theta} \right) \right]$$

$$\approx \left( J_r \left( (1 + \lambda_b + \lambda_e) \frac{1}{2} \phi + J_r^{-1}(\frac{1}{2} \phi)^2 \tilde{\theta} \right) \right)$$

Thus, we have the following:

$$\frac{\delta}{\delta_i \theta} = J_r \left[ (1 + \lambda_b + \lambda_e) \text{Logv}((\frac{2}{1} \tilde{\theta})) \right] \left( J_r^{-1}(\frac{1}{2} \phi)^2 \tilde{\theta} \right)$$

E.2: $\frac{\delta \mathbf{p}_e}{\delta_i \theta}$ Jacobian Derivation

To find $\frac{\delta \mathbf{p}_e}{\delta_i \theta}$ we perturb the measurement function by a error angle $\frac{2}{1} \tilde{\theta}$ and define $\frac{1}{2} \mathbf{R} \approx \text{Expv}(\frac{-2}{1} \tilde{\theta})^2 \hat{\mathbf{R}}$.

$$\frac{b}{b} \mathbf{p}_e + \frac{b}{b} \tilde{\mathbf{p}}_e = (1 + \lambda_b + \lambda_e) \text{Expv} \left[ - \lambda_b \text{Logv} \left( \text{Expv}(\frac{-2}{1} \tilde{\theta})^2 \hat{\mathbf{R}} \right) \right] \mathbf{p}_2$$

$$\approx (1 + \lambda_b + \lambda_e) \text{Expv} \left[ - \lambda_b \frac{1}{2} \mathbf{R} (\frac{2}{1} \tilde{\theta}) \right] \mathbf{p}_2$$

By applying Equation 28 and defining $\text{Logv}((\frac{2}{1} \tilde{\theta})) \approx \frac{1}{2} \phi$ we get:

$$\approx (1 + \lambda_b + \lambda_e) \text{Expv} \left[ \lambda_b \frac{1}{2} \phi + J_r^{-1}(\frac{1}{2} \phi)^2 \tilde{\theta} \right] \mathbf{p}_2$$

Applying Equation 27 we get:

$$\approx (1 + \lambda_b + \lambda_e) \text{Expv} \left[ J_r \left( \lambda_b \frac{1}{2} \phi \right) \lambda_b J_r^{-1}(\frac{1}{2} \phi)^2 \tilde{\theta} \right] \mathbf{p}_2$$
Finally we can apply the small angle Equation 29 and the properties of a skew symmetric, see 22, we get:

\[
\approx (1 + \lambda_b + \lambda_e) \text{Expv} \left[ \lambda_b^0 \phi \right] \left( I_{3 \times 3} + \left[ J_r(\lambda_b^0 \phi) \lambda_b J_r^{-1}(\frac{1}{2} \phi) \right] \right) {\hat{p}}_2 \\
\approx {\hat{p}}_e - (1 + \lambda_b + \lambda_e) \text{Expv} \left[ \lambda_b^0 \phi \right] \left( {\hat{p}}_2 \times \right) J_r(\lambda_b^0 \phi) \lambda_b J_r^{-1}(\frac{1}{2} \phi) \phi \hat{\theta} 
\]

Thus, we have the following:

\[
\frac{\delta b \hat{p}_e}{\delta ^1 \hat{\theta}} = -(1 + \lambda_b + \lambda_e) \text{Expv} \left[ \lambda_b \text{Logv}(2 \hat{R}) \right] \left( {\hat{p}}_2 \times \right) J_r(\lambda_b \text{Logv}(2 \hat{R})) \lambda_b J_r^{-1}(\text{Logv}(2 \hat{R})) 
\]

E.3: $\frac{\delta b \hat{p}_e}{\delta ^1 \hat{p}_2}$ Jacobian Derivation

To find $\frac{\delta b \hat{p}_e}{\delta ^1 \hat{p}_2}$ we perturb the measurement function by a error angle $1 \hat{p}_2$.

\[
b \hat{p}_e + b \hat{p}_e = (1 + \lambda_b + \lambda_e) \text{Expv} \left[ -\lambda_b \text{Logv} \left( \hat{R} \right) \right] \left( {\hat{p}}_2 + 1 \hat{p}_2 \right) \\
= b \hat{p}_e + (1 + \lambda_b + \lambda_e) \text{Expv} \left[ -\lambda_b \text{Logv} \left( \hat{R} \right) \right] {\hat{p}}_2 
\]

Thus, we have the following:

\[
\frac{\delta b \hat{p}_e}{\delta ^1 \hat{p}_2} = (1 + \lambda_b + \lambda_e) \text{Expv} \left[ -\lambda_b \text{Logv} \left( \hat{R} \right) \right] 
\]

RPNG-2017-ASYNC 25
Appendix F: Covariance for ORB-SLAM Pose

The goal is to arbitrary construct a covariance based on information provided on the current pose. We naively assume that the information of global features in the environment are only a function of the current pose. Thus we look to construct the covariance based on the following measurement model of a feature seen in the global in the left and/or right stereo camera.

\[
L_{p_f} = L_{G} R (G_{p_f} - G_{p_L}) \tag{122}
\]

\[
R_{p_f} = R_{L} L_{G} R (G_{p_f} - G_{p_L}) + R_{p_L} \tag{123}
\]

where we have denoted the position of the feature seen in the undistorted right camera frame rotated and translated as follows:

\[
R_{L} = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix} \tag{124}
\]

\[
R_{p_L} = [f_{\text{baseline}} \ 0 \ 0] \tag{125}
\]

To calculate the covariance we can perform the following summation over all features:

\[
P = \left[ \sum_{i=1}^{k} H_{i}^{T} \Lambda^{-1} H \right]^{-1} = \left[ \sum_{i=1}^{k} (H_{1} H_{2})^{T} \Lambda^{-1} H_{1} H_{2} \right]^{-1} \tag{126}
\]

where \( k \) is the total number of features and \( \Lambda \) is the zero-mean white Gaussian of the measurements. We can define the jacobians for both features seen in the left and right camera frames as the following:

\[
H_{L1} = \begin{bmatrix}
1 & 0 & -\frac{L_{p_f}(1)}{L_{p_f}(3)^2} \\
0 & 1 & -\frac{L_{p_f}(2)}{L_{p_f}(3)^2} \\
\frac{L_{p_f}(3)}{L_{p_f}(3)} & \frac{L_{p_f}(3)}{L_{p_f}(3)} & 0
\end{bmatrix} \tag{127}
\]

\[
H_{L2} = \begin{bmatrix}
[ L_{p_f} \times ] & -L_{G} R
\end{bmatrix} \tag{128}
\]

\[
H_{R1} = \begin{bmatrix}
1 & 0 & -\frac{R_{p_f}(1)}{R_{p_f}(3)^2} \\
0 & 1 & -\frac{R_{p_f}(2)}{R_{p_f}(3)^2} \\
\frac{R_{p_f}(3)}{R_{p_f}(3)} & \frac{R_{p_f}(3)}{R_{p_f}(3)} & 0
\end{bmatrix} \tag{129}
\]

\[
H_{R2} = \begin{bmatrix}
R_{L} [ L_{p_f} \times ] & -R_{L} L_{G} R
\end{bmatrix} \tag{130}
\]

Finally we can define our noise matrix \( \Lambda \) as the following:

\[
\Lambda = \begin{bmatrix}
\frac{1}{(f_x)^2} & 0 \\
0 & \frac{1}{(f_y)^2}
\end{bmatrix} \tag{131}
\]

where \( f_x \) and \( f_y \) are the focal lengths in the x and y directions respectively. We now have all values needed to calculate the covariance for a given pose in ORB-SLAM. We can use the following algorithm structure to calculate the final covariance.
1: procedure CALC_ORB_COVARIANCE($L^G R^G p^G L, R^R p^R L, \text{features}$)
2:     $A \leftarrow 0_{6 \times 6}$
3:     $\Lambda \leftarrow \text{eq (131)}$
4:     for each feature do
5:         $L^p_f \leftarrow \text{eq. (122)}$
6:         $R^p_f \leftarrow \text{eq. (123)}$
7:         if feature seen in left then
8:             $H_{L1} \leftarrow \text{eq. (127)}$
9:             $H_{L2} \leftarrow \text{eq. (128)}$
10:            $A \leftarrow A + (H_{L1} H_{L2})^\top \Lambda^{-1} H_{L1} H_{L2}$
11:        end if
12:        if feature seen in right then
13:            $H_{R1} \leftarrow \text{eq. (129)}$
14:            $H_{R2} \leftarrow \text{eq. (130)}$
15:            $A \leftarrow A + (H_{R1} H_{R2})^\top \Lambda^{-1} H_{R1} H_{R2}$
16:        end if
17:     end for
18:     return $A^{-1}$
19: end procedure
Appendix G: Covariance for LOAM Pose

Given the most recent odometry measurement and corresponding lidar point cloud from the LOAM package we would like to create a corresponding covariance. In this case we look at the feature found in the first lidar point cloud projected into a matching point in the second point cloud.

\[ \mathbf{2} \mathbf{p}_f = \mathbf{2} \mathbf{R} (\mathbf{1} \mathbf{p}_f - \mathbf{1} \mathbf{p}_2) \]  

(132)

where \( \mathbf{2} \mathbf{R} \) and \( \mathbf{1} \mathbf{p}_2 \) are the relative transforms from LOAM and \( \mathbf{1} \mathbf{p}_f \) is a 3d point from the matching lidar pointcloud. From this we want to compute the covariance based on the summation over all matched lidar point cloud features:

\[ \mathbf{P} = \left[ \sum_{i=1}^{k} \mathbf{H}^{\top} \Lambda^{-1} \mathbf{H} \right]^{-1} \]  

(133)

where \( k \) is the total number of features and \( \Lambda \) is the zero-mean white Gaussian of the measurements.

We can define the jacobian as follows:

\[ \mathbf{H} = \begin{bmatrix} [\mathbf{2} \mathbf{p}_f \times] & -\mathbf{2} \mathbf{R} \end{bmatrix} \]  

(134)

Finally we can define our noise matrix \( \Lambda \) as the following:

\[ \Lambda = \begin{bmatrix} 2\sigma_x^2 & 0 & 0 \\ 0 & 2\sigma_y^2 & 0 \\ 0 & 0 & 2\sigma_z^2 \end{bmatrix} \]  

(135)

where we define \( \sigma_x, \sigma_y, \sigma_z \) as the noise sigma (in meters) in the x, y, and z-axis respectively. The sigmas are multiplied by two since both \( \mathbf{1} \mathbf{p}_f \) and \( \mathbf{2} \mathbf{p}_f \) are affected by this noise. For our Velodyne we have chosen a noise respective to 5cm accuracy. We can use the following algorithm structure to calculate the final covariance.

1: procedure CALC_LOAM_COVARIANCE(\( \mathbf{2} \mathbf{R}, \mathbf{1} \mathbf{p}_2, \text{points} \))
2: \( \mathbf{A} \leftarrow \mathbf{0}_{6 \times 6} \)
3: \( \mathbf{A} \leftarrow \text{eq (135)} \)
4: for each point do
5: \( \mathbf{2} \mathbf{p}_f \leftarrow \text{eq. (132)} \)
6: \( \mathbf{H} \leftarrow \text{eq. (134)} \)
7: \( \mathbf{A} \leftarrow \mathbf{A} + \mathbf{H}^{\top} \Lambda^{-1} \mathbf{H} \)
8: end for
9: return \( \mathbf{A}^{-1} \)
10: end procedure

RPNG-2017-ASYNC 28
