

Delaware Soybean Variety Trials 2024

Gunnar Isaacs
Associate Scientist
Variety Testing

Carvel Research and Education Center
16483 County Seat Highway
Georgetown, DE 19947

Commercial companies or products are mentioned in this publication solely for the purpose of providing specific information. Mention of a company or product does not constitute a guarantee or warranty of products by the Agricultural Experiment Station or Delaware Cooperative Extension or an endorsement over products of other companies not mentioned.

Acknowledgments

Thank you to all the companies who have supported and participated in the 2024 University of Delaware Soybean Variety Trials.

We are indebted and extend appreciation to the following cooperators who generously provided land and support for our off-site locations. They are Craig Murray of Murray Bros. Farm in Selbyville, Rob Emerson of Emerson Farms in Middletown and Mark Davis of Davis Farms in Georgetown.

I would like to personally thank Buddy Willey, Ward Harris, George Petitgout, Kyler Lecates, Chad Messick, Justin Jameson and Brian Hearn of our Carvel Farm Staff for their assistance in managing the trials. These trials would not have been possible without their contributions.

Methodology

All trials were conducted in a randomized, complete block design with four total replications. The final plot length of all trials was 17 ft. More experimental details such as population, plot width, planting/harvest dates, and tillage or cultural practices can be found in the following table. Temperature and rainfall information for the growing season can be accessed at the nearest test locations from DEOS <http://www.deos.udel.edu/>

C.V. and L.S.D.

The coefficient of variation (C.V.) is a measurement of the amount of uncontrollable variability due to differences in the soil, weather, fertility, etc. The acceptable CV level is dependent on the field of the research. Medicine and pharmaceutical research have stricter CV ranges than research in agricultural sciences due to more control over outside variables. The American Association for Clinical Chemistry in ***Clinical Chemistry, Volume 35, Issue 4*** defines for agricultural studies that CV<10 is very good, 10-20 is good, 20-30 is acceptable. Please note that the C.V. is expected to be higher at dryland locations.

The least significant difference (L.S.D.; computed at a 5% level of probability) is a tool to determine if two average values are significantly different. The difference between two varieties must exceed the L.S.D. value to be considered significantly different from one another.

HOW TO BEST USE SOYBEAN VARIETY TRIAL INFORMATION

Information presented in this summary may be useful in selecting soybean varieties for production in Delaware. To maximize the usefulness of this information, follow these suggestions:

1. Select the test location that best represents your production location. Generally, varieties are adaptable across Delaware but certain soil or climatic conditions, cultural practices, or insect/disease problems may limit the choice.
2. Multiple-year average (means) across the greatest number of years are the best predictors of performance. Refer to previous test reports for information to evaluate soybean varieties which are of interest to you. Comparison between your selected variety and the grand mean for your closest test location will be helpful in identifying superior varieties for your area.
3. Check the grand mean for the long-term averages and compare with your own production experience. If your yields have been consistently below these grand mean levels, you should evaluate each part of your management system for potential areas of improvement.

Summary of Results

In 2024, the Delaware Soybean Variety Trial's yield averages were 82, 77, 43, and 79 Bu/acre across four statewide testing locations compared to the 2023 yields which averaged 78, 75, 53, and 80 Bu/acre. The grain yield average across all four locations in 2024 was almost identical to 2023 yields, with less than a 2% difference.

However, this is somewhat misleading without data analysis and can primarily be contributed to the overall yield performance at the Middletown dryland location. Yields at this location in 2024 were 10 Bu/acre lower and down 23% than in 2023 which brought the overall statewide average down significantly. This dryland location received a total of 0.22 inches of rain from June 7 to June 29 and 0 inches of rain from July 1 to July 10. This earlier extended drought affected early growth development and vigor of the soybeans. Another dry stretch occurred with this location only receiving 0.16 inches of rainfall from August 10-31 during the key reproductive stage of development. The Middletown location only received 1.63 inches of rain total for the entire month of August while the daily high temperature average for August was 83.9 degrees. This combination of weather events certainly affected the flowering and pod development stages of the soybeans negatively.

2024 yield averages across the two irrigated sites in Georgetown and Harrington were 2.4% higher than 2023, with a 2 Bu/acre increase. The Dagsboro location yield average remained relatively unchanged between 2024 and 2023.
